Abstract of the Disclosure

A microscopic image capture apparatus and a microscopic image capturing method allow a wide-5 angle field and high-precision microscope digital image to be efficiently captured. First, the entire area of a slide glass on a stage is divided into field size sections (low-magnification sections) of objective lens, low-powered the 10 sequentially transferred perpendicular to an optical axis, image information is obtained for each low-magnification section of the entire area, low-magnification section is divided high-magnification size sections (high-15 magnification sections), a high-magnification image is captured using a high-powered objective lens a high-magnification section only on including simultaneously in the high-magnification sections, high-magnification image is generated 20 correctly maintaining the relative position between the obtained image information and the area of a high-magnification section which is not captured, high-magnification and а composite image information about a sample on the slide glass is 25 generated.
